During the editing process, a `_layer_` is an individual element that holds a specific area of an image. Layers and their properties are discussed in more detail in Chapter 6. After you create a new file with Photoshop, you'll find that you have a single layer on top of the background. You can move, duplicate, or delete layers, and you can use them to manipulate an image. After creating the first image, open a new file for the second, and continue in this fashion.

Q: Evaluate integral $\int_0^{\infty} \frac{\sinh(ax)}{e^{ax}+e^{-ax}} \cdot \frac{\sinh(bx)}{e^{bx}+e^{-bx}} dx$ How to evaluate: $\int_0^{\infty} \frac{\sinh(ax)}{e^{ax}+e^{-ax}} \cdot \frac{\sinh(bx)}{e^{bx}+e^{-bx}} dx$ Maybe the best way is to find a relation between this integral and the incomplete Beta function and then to integrate using it but I don't see how. Also, I don't know how to use Mathematica properly. The present invention relates to a small scale, high capacity, effective and safe furnace and, more particularly, to a modular transportable furnace that can be used for processing large quantities of materials, such as the incineration of waste materials. The collection of solid waste and the determination of the classification of particular waste materials has been an area of concern for many years. The incineration of hazardous waste has also been an area of concern for many years. This concern has been heightened over the last decade as the waste accumulation problem has grown in size, and these materials are much more technically hazardous than in the past. Incineration can be achieved in several ways. For example, hazardous wastes may be burned in the presence of a combustion inhibitor, such as the addition of a liquid to the flue gases to control the flue gas temperature at the outlet end of a furnace. The combustion of hazardous wastes is accomplished in the presence of oxygen and a combustion inhibitor, i.e., a material that reacts with combustion. Common combustion inhibitors include liquid chemicals, mixtures, etc. that are designed to chemically alter and/or destroy combustion. Common combustion inhibitors include heavy metals, herbicides and pesticides. Other combustion inhibitors are proposed, as disclosed in applicant's co-pending patent application Ser. No. 08/835,280, filed Apr. 18, 1997, entitled "Inhibiting Oxidation of Fossil Fuel Combustion by Hydrogen Fluoride." Incineration has long been accomplished using a stationary furnace. A stationary furnace has a constant inner chamber or furnace (also referred to herein as the reactor), usually between about eight and thirty feet in diameter and several hundred feet high. The gases generated in a stationary furnace must rise, because stationary furnaces have a constant volume chamber. Stationary furnaces generate undesirable turbulence and aerodynamic drag forces. Moreover, the gases generated in the stationary furnace can become too hot to safely transport. In addition, temperature gradients from the furnace inlet to the furnace outlet can lead to corrosion of the structures in the furnace, which is especially undesirable when the flue gas temperatures are between 650°C and 850°C. When the discharge temperature of a stationary furnace exceeds about

1250xc2x0 F., the gas above the melting point of water is in the saturated super-heated state, and condensation of the gas above 1250xc2x0
