Electrical motors are used in a wide variety of applications, ranging from household appliances, such as clothes washers and dryers, to industrial machinery, such as conveyor belts, chain-driven assemblies, and other mechanisms, such as conveyor belts. The motor typically has a rotor that is coupled to an output shaft that is connected to the mechanism to be driven. A stator is typically formed of a core and a plurality of windings, or coils, about the core. The core generally has a cylindrical outer surface and a cylindrical inner surface. The windings are generally made up of a plurality of conductors that are wound in a specified pattern to define the core. Current is provided to the windings to induce a magnetic field that interacts with the rotor, thereby driving the rotor and the output shaft, which may be coupled thereto. The position of the rotor can be detected to estimate the current and/or position of the rotor. The speed of operation of the motor is typically controlled by regulating the amount of current flowing through the motor. However, the speed and torque of the motor often deviate from the desired speed and torque due to variations in the temperature of the motor. For example, the motor may operate at the desired torque at a low speed due to ambient temperature, but as the temperature increases, the motor may become subject to stalling. A motor stall is typically defined as a condition in which the motor cannot produce the desired torque due to the current flowing through the windings. In addition to stalling, the magnetic field of the motor may also become distorted if the speed is too slow or
